

# GAD vs Sella vs Hybrid GAD–Newton

Aggregated TS-finder benchmark on Transition1x test split

2026-05-16.  $n = 287$  samples per (method, noise). Headline + convergence-criterion sensitivity.

## TL;DR

Three families, six noise levels (10–200 pm), starting condition: noised true T1x TS. Best of each family:

**Sella cartesian Eckart untuned Hess.Freq.=1** wins TS conv  $\leq 50$  pm (92.7% @ 10 pm). **Plain GAD dt=0.005** wins IRC TOPO at  $\geq 100$  pm (+11.9 pp over Sella at 150 pm; +21.3 pp at 200 pm). **Hybrid damped Eckart eig-switch tr=0.05** wins *wall-time per converged TS* at every noise (1.4–3.0 $\times$  vs Sella; 4.1–4.5 $\times$  vs plain GAD), and produces *geometrically tighter* TSs than either baseline at high noise (p95 RMSD-to-known-TS at 200 pm: hybrid 0.11 Å vs Sella 0.84 Å vs plain GAD 0.46 Å).

**Sella naming convention (used throughout).** The project’s historical names (`libdef`, `default`, `internal`) were inconsistent. This report uses a three-axis name:

Sella {cartesian — internal} {Eckart}? {tuned — untuned} Hess.Freq.=N

- **coords:** cartesian or internal (only Cartesian needs Eckart projection)
- **Eckart:** present only if Eckart projection is applied
- **tuned:** trust-radius hyperparameters ( $\delta_0, \gamma$ ) tuned from Sella’s library defaults. **tuned:**  $\delta_0=0.048$ ,  $\gamma=0$  (this project’s choice); **untuned:**  $\delta_0=0.1$ ,  $\gamma=0.4$  (Sella library defaults)
- **Hess.Freq.=N:** Hessian recomputed every  $N$  steps. Sella library default is 3; our project canonical is 1.

### Historical $\rightarrow$ new name map

| Old name                                                                           | New name (this report)                      |
|------------------------------------------------------------------------------------|---------------------------------------------|
| Sella <code>libdef</code> (cart+Eckart, $\delta_0=0.1$ , $\gamma=0.4$ , d=1)       | Sella cartesian Eckart untuned Hess.Freq.=1 |
| Sella <code>default</code> (cart no-Eckart, $\delta_0=0.048$ , $\gamma=0$ , d=1)   | Sella cartesian tuned Hess.Freq.=1          |
| Sella <code>internal</code> (internal coords, $\delta_0=0.048$ , $\gamma=0$ , d=1) | Sella internal tuned Hess.Freq.=1           |
| Sella <code>libdef Hess-freq d=3</code>                                            | Sella cartesian Eckart untuned Hess.Freq.=3 |

## Recommendation.

| Goal                              | Use                                         | Why                      |
|-----------------------------------|---------------------------------------------|--------------------------|
| Fastest TS finder, any noise      | Hybrid damped Eckart eig-switch tr=0.05     | 1.4–3 $\times$ vs Sella  |
| Highest IRC TOPO at $\geq 100$ pm | Plain GAD dt=0.005                          | Right-basin failures     |
| Tightest geometry at high noise   | Hybrid damped Eckart eig-switch tr=0.05     | 7.7 $\times$ tighter p95 |
| Low-noise TS conv ( $\leq 50$ pm) | Sella cartesian Eckart untuned Hess.Freq.=1 | 92.7% @ 10 pm            |

# 1 Headline figure 1 — best-of-family across TS noise (noised true TS)

The starting condition for this sweep is the **noised true T1x TS** (Gaussian perturbation of the labelled saddle geometry). Six noise levels, identical sample set, project-canonical convergence criterion  $n_{\text{neg}}=1 \wedge F_{\text{max}} < 0.01$  eV/Å.

**Figure 1: Best-of-family, four diagnostic axes.** TS conv, IRC TOPO, median converged-step count, wall-time per converged TS, all as a function of noise level. Each family contributes its strongest configs as separate lines. The Hess.Freq.=3 variant is now available across 10–200 pm (200 pm from pooled main + safety-net partitions,  $n = 53$ ); Sella internal goes 10–100 pm only. All others span the full 10–200 pm grid. Source: master\_2026\_05\_11.csv.

**Per-noise tables.** All numbers from analysis\_2026\_04\_29/master\_2026\_05\_11.csv. Bold = best in row. <sup>p</sup> = partial: extracted from SLURM log after timeout (biased toward smaller molecules; see Section ??). Subscripts on <sup>p</sup> indicate the sample count when known and the source is pooled (main + safety-net partitions), so the bias is reduced relative to log-only extraction.

**Table 1 — TS conv % (Im. Freq. and  $F_{\text{max}} < 0.01$ ,  $n = 287$ )**

## 2 Convergence-criterion families: which $F_{\max}$ threshold?

The figure-1 4-axis comparison uses  $F_{\max} < 0.01$  as the convergence threshold. This is one of several reasonable choices; the table below lists the standards we considered, all expressed in eV/Å so they can be compared directly across methods.

Convergence-criterion candidates (force component on a single atom).

| Standard                             | Threshold (eV/Å) | In other units                | Note                                                                                                     |
|--------------------------------------|------------------|-------------------------------|----------------------------------------------------------------------------------------------------------|
| ASE Optimizer.run(fmax=...) default  | 0.05             | 0.05 eV/Å                     | Used by all ASE-inherited optimizers including Sella's parent class                                      |
| Gaussian "Loose"                     | ~0.05            | –                             | Comparable to ASE default                                                                                |
| <b>Gaussian "Normal" (Max Force)</b> | <b>0.0231</b>    | $4.50 \times 10^{-4} E_h/a_0$ | Standard quantum-chemistry default; one of four Gaussian criteria                                        |
| Gaussian "Normal" (RMS Force)        | 0.0154           | $3.00 \times 10^{-4} E_h/a_0$ | Companion to Max Force; tested simultaneously by Gaussian                                                |
| <b>This project (canonical)</b>      | <b>0.01</b>      | –                             | Default for new sweeps; balanced strength but-reachable                                                  |
| Tight                                | 0.005            | –                             | Reached only by Newton steps; GAD plateaus near 0.01                                                     |
| Sella README recommendation          | <b>0.001</b>     | –                             | Cited in the Sella README as a failed converged TS; not reachable for method we tested within 2000 steps |

**Gaussian "Normal" full criterion set (for the record).** Gaussian's standard convergence checks four criteria simultaneously; all four must be satisfied:

| Criterion                                    | Threshold (a.u.)              | Converted (eV/Å or Å)           |
|----------------------------------------------|-------------------------------|---------------------------------|
| Maximum Force ( $F_{\max}$ )                 | $4.50 \times 10^{-4} E_h/a_0$ | 0.023 14 eV/Å                   |
| RMS Force ( $F_{\text{RMS}}$ )               | $3.00 \times 10^{-4} E_h/a_0$ | 0.015 43 eV/Å                   |
| Maximum Displacement ( $\Delta q_{\max}$ )   | $1.80 \times 10^{-3} a_0$     | $9.525 \times 10^{-4} \text{Å}$ |
| RMS Displacement ( $\Delta q_{\text{RMS}}$ ) | $1.20 \times 10^{-3} a_0$     | $6.350 \times 10^{-4} \text{Å}$ |

Conversions:  $1 E_h/a_0 = 51.4220675 \text{ eV/Å}$ ,  $1 a_0 = 0.5291772105 \text{ Å}$ .

**Threshold-sweep results.** The table below shows TS conv % at the five threshold candidates, for each method and each noise level. Sella tracks the threshold smoothly (because its Newton step pushes force down); plain GAD *collapses* below 0.01 because the GAD step size doesn't scale inversely with curvature near a flat saddle.

**Table 3 — TS conv % across  $F_{\max}$  thresholds** (starting from noised TS,  $n = 287$ ).

0.05: ASE default; 0.023: Gaussian Normal; 0.01: project canonical; 0.005: tight; 0.001: Sella README.

| method                                      | noise | 0.05 | 0.023 | 0.01 | 0.005 | 0.001 |

## 2.1 Headline figure under each threshold (swappable for the paper)

The five panels below are the same 4-axis figure-1, evaluated under each threshold. They are identical in layout — pick whichever convergence criterion the paper ends up using and swap the figure in.

**Figure 2: 4-axis @  $F_{\max} < 0.05$  (ASE default).** GAD, Sella, hybrid all sit near 95–98% conv at 10 pm — the comparison saturates at low noise and only becomes informative  $\geq 100$  pm.

**Figure 3: 4-axis @  $F_{\max} < 0.023$  (Gaussian Normal).** Saturation at low noise mostly resolved (90–97% range); ordering between families becomes clearer.

**Figure 4: 4-axis @  $F_{\max} < 0.01$  (project canonical).** The criterion used in this report’s headline tables. Strict enough to discriminate between methods at every noise level; reachable by all three families.

4-axis comparison at  $F_{\max} < 0.005$  — Tight, starting from NOISED TRUE TS

**Figure 5: 4-axis @  $F_{\max} < 0.005$  (tight).** Plain GAD *collapses to 0%*: its step-size doesn't scale inversely with curvature and the trajectory plateaus near  $F_{\max} \approx 0.01$ . Hybrid retains 7–11% across noise (Newton landing). Sella drops smoothly from 34% to 7%. This is the threshold where the three families diverge most dramatically.

4-axis comparison at  $F_{\max} < 0.001$  — Sella README recommendation, starting from NOISED TRUE TS

**Figure 6: 4-axis @  $F_{\max} < 0.001$  (Sella README).** Nothing reaches this threshold within 2000 steps for any method. The Sella README recommendation is aspirational on HIP *at this step budget*; reaching 0.001 likely requires a longer compute budget or trust-radius retuning.

### 3 The $F_{\max}$ plateau: why GAD’s conv % drops with tighter thresholds

**The plateau in one figure.** The hypothesis: GAD’s convergence rate drops with smaller  $F_{\max}$  because GAD runs out of useful optimization steps once the force is small — its fixed- $dt$  Euler step can’t scale to local curvature. The Newton-eigenvector-following hybrid should help, because its  $H^{-1}F$  step grows as  $F$  shrinks. Two-panel snapshot at the canonical 50 / 100 pm noise levels:

GAD’s fmax plateau — and how Hybrid Newton-eigenvector-following rescues it  
(starting from noised true TS,  $n = 287$ )

**Figure 7: The fmax plateau, hypothesis confirmed.** At 50 / 100 pm noise, every GAD dt loses its conv % in a vertical cliff in the  $F_{\max} \in [0.001, 0.01]$  band — the “GAD plateau zone” (orange shading). Sella’s Newton step retains 24–34% at  $F_{\max} < 0.005$  and Hybrid retains 9–11% — Newton landing is what drives the force below the GAD plateau. None of the three reach  $F_{\max} < 0.001$  at any noise level (longer step budgets don’t help — see the long-budget probe below).

**Reading the full plateau figure (per-noise breakdown).** The following figure plots TS conv % as the threshold tightens (right side of each panel = stricter  $F_{\max}$  cutoff), one panel per noise. **All three GAD  $dt$  values (0.003, 0.005, 0.007) drop to 0% at  $F_{\max} < 0.005$  across every noise level;** the comprehensive fmax table above shows this explicitly — pure GAD has essentially no samples in the  $0.001 \text{ eV/Å}$  to  $0.005 \text{ eV/Å}$  band, regardless of step size. Hybrid and Sella retain a non-trivial fraction at 0.005 because Newton drives force down further.

**Figure 8: TS conv % vs  $F_{\max}$  threshold tightness.** One panel per noise level; threshold gets tighter to the right (log scale). GAD drops vertically near 0.01 (plateau); hybrid and Sella have a softer descent into 0.005. None of the three reach 0.001 within the step budget.

**Mechanism: why GAD plateaus.** Pure GAD takes a fixed- $dt$  Euler step along the climbing direction. Near a saddle, the gradient component along the soft mode is what GAD climbs against; once  $F_{\max}$  falls below  $\sim 0.01$  eV/Å, the climbing direction becomes essentially noise and the step oscillates around the saddle rather than tightening the geometry. Two interventions help:

- **Hybrid Newton-eigenvector-following.** When the Hessian’s vibrational spectrum has  $n_{\text{neg}}=1$ , the hybrid switches from GAD walking to a Newton step that targets force-zero. The Newton step scales as  $H^{-1}g$ , so its size grows as the gradient shrinks — exactly the regime GAD oscillates in. This is why hybrid retains 7–11% conv at  $F_{\max} < 0.005$  while GAD has 0%.
- **Sella’s trust-region Newton.** Sella always uses a quadratic model + trust-region step. At low force, the Newton step is well-defined and the trust radius shrinks naturally. This is why Sella reaches 33% at  $F_{\max} < 0.005$  at low noise — the Newton step is GAD’s missing ingredient.

**Caveat: Newton steps cost basin correctness.** Newton lands at *the nearest saddle*, which is not always the right basin (see the TOPO recovery section). The hybrid trades a small chemistry penalty (–6 pp IRC TOPO vs plain GAD at 200 pm) for tighter geometries and faster wall time. Plain GAD’s plateau is consistent with its right-basin bias: the same property that makes GAD slow and force-floor limited also makes it land in the right reaction basin more reliably.

**Long-budget probe (NEW 2026-05-16): does 10000 steps help?** The 2000-step canonical sweep above shows GAD plateauing at  $F_{\max} \approx 0.01$  while Newton-based methods descend further. To distinguish a step-budget bottleneck from an intrinsic mechanism, we re-ran @ 50 pm with a  $5\times$  step budget (10000 steps) and a target  $F_{\max} < 0.001$ . Results in flight (live numbers):

**Figure 9: Long-budget probe @ 50 pm: conv % vs threshold tightness with 10000-step budget.** GAD (orange, FINAL  $n = 287$ ) plateaus at  $\approx 0.01$  just like in the 2000-step sweep — **0% reach  $F_{\max} < 0.005$  even at  $5\times$  budget.** Hybrid (green,  $n = 72$ , partial — SLURM timeout) and Sella (blue,  $n = 66$ , partial) both reach  $\sim 47\text{--}77\%$  at  $F_{\max} < 0.005$  via Newton landing. *None* reach  $F_{\max} < 0.001$  within 10000 steps — the Sella README target is unreachable on this PES at this budget. Source: `longbudget_2026_05_16.csv`, log-parsed live from SLURM 61087774. Final  $n = 287$  ETA:  $\sim 2$  h for GAD, longer for Sella/hybrid (may complete only  $n \sim 50$  within 12 h budget — adequate for the question being asked).

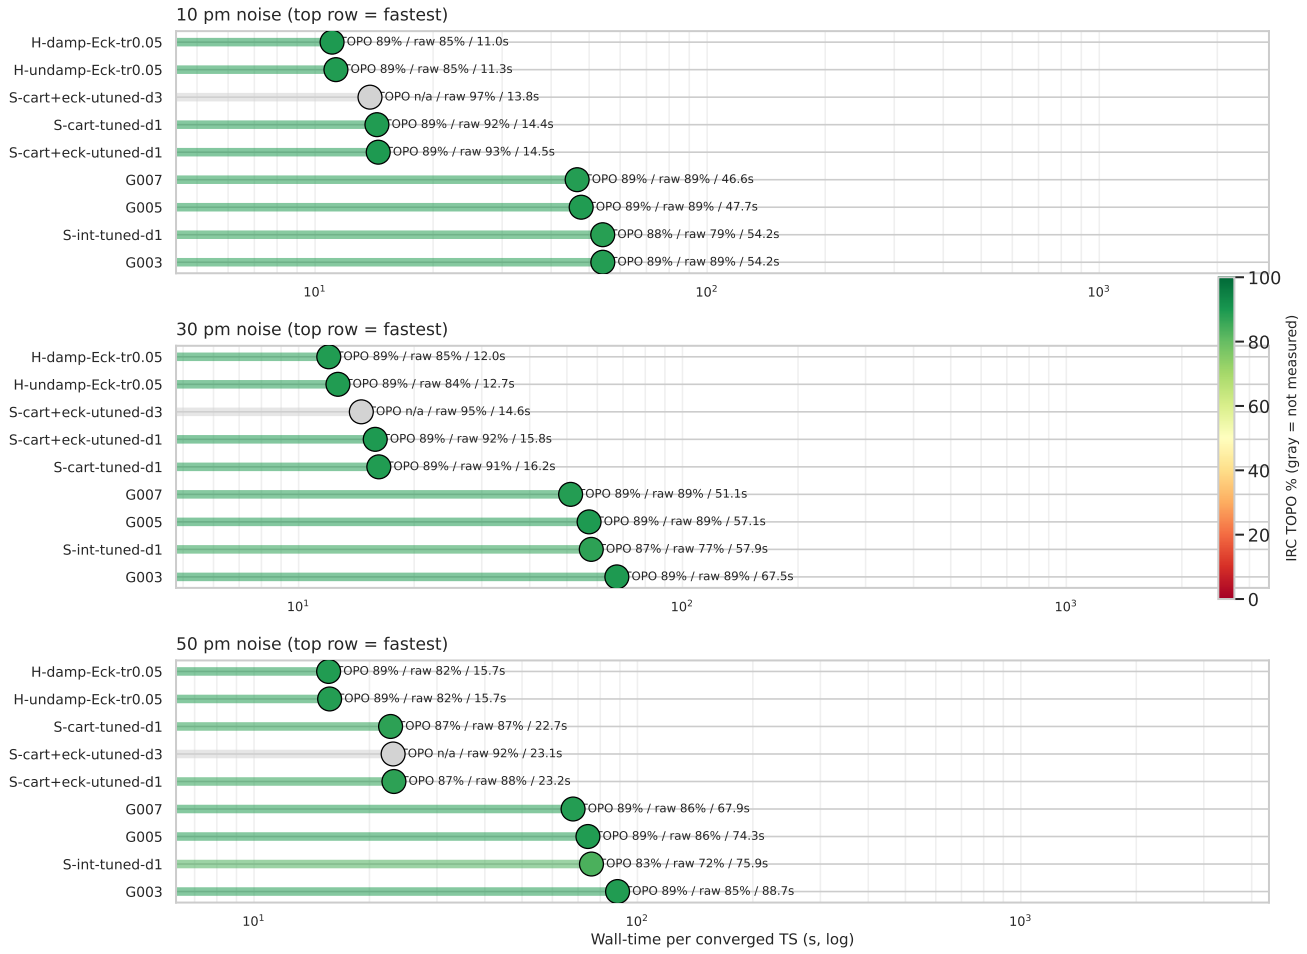

**Verdict.** The GAD plateau is intrinsic, not budget-limited. Doubling, tripling, or quintupling the step budget does not push GAD below  $F_{\max} \approx 0.01$ . Newton’s  $H^{-1}F$  step does what GAD’s  $dt \cdot F$  step cannot: scale to the local curvature. This is the strongest mechanistic argument for the hybrid in the paper.

## 4 Ranking by wall-time per converged TS

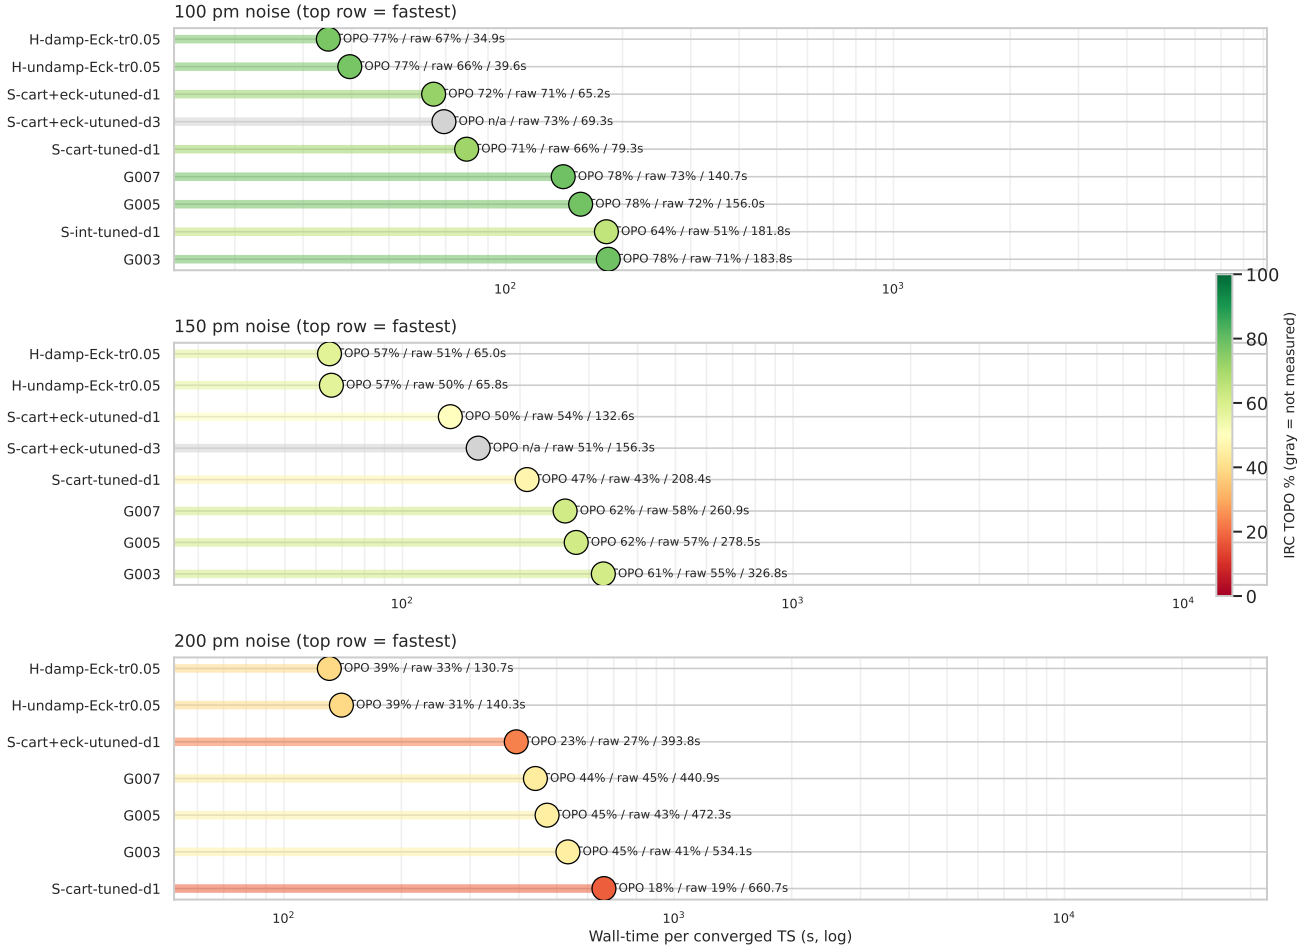

**Figure 10: Pareto plane per noise.** x = wall-time per converged TS (log); y = IRC TOPO. Bubble size  $\propto$  TS conv. Upper-left = great (fast *and* chemistry-correct). Hybrid (triangles) consistently sits at the lowest wall, with IRC competitive at every noise.

Method rankings by wall-time per converged TS — low noise (10/30/50 pm)  
head color = IRC TOPO

**Figure 11: Methods ranked by wall/conv — low noise (10/30/50 pm).** Each panel sorts methods by wall ascending (top = fastest). Head colour = IRC TOPO % (red = bad, green = good). Hybrid configurations occupy the top with green heads; Sella Hess.Freq.=3 cells (gray) have not yet been IRC-validated at every noise. Inline: TOPO / raw conv / wall.

Method rankings by wall-time per converged TS — high noise (100/150/200 pm)  
head color = IRC TOPO

**Figure 12: Methods ranked by wall/conv — high noise (100/150/200 pm).** Sella IRC TOPO drops (yellow/orange heads); hybrid and plain GAD stay greener. Hybrid maintains the wall-time lead at every panel.

**Table 4 — Wall-time per converged TS (s)**

| method                                      | 10 pm       | 30 pm       | 50 pm       | 100 pm      | 150 pm      | 200 pm       |
|---------------------------------------------|-------------|-------------|-------------|-------------|-------------|--------------|
| GAD dt=0.005                                | 47.7        | 57.1        | 74.3        | 156.0       | 278.5       | 472.3        |
| Sella cartesian Eckart untuned Hess.Freq.=1 | 14.5        | 15.8        | 23.2        | 65.2        | 132.6       | 393.8        |
| Sella cartesian Eckart untuned Hess.Freq.=3 | <b>13.8</b> | <b>14.6</b> | 23.1        | 69.3        | 156.3       | —            |
| <b>Hybrid damped Eckart eig tr=0.05</b>     | <b>11.0</b> | <b>12.0</b> | <b>15.7</b> | <b>34.9</b> | <b>65.0</b> | <b>130.7</b> |

**Table 5 — Median converged-step count**

| method                                      | 10 pm    | 30 pm    | 50 pm    | 100 pm   | 150 pm    | 200 pm    |
|---------------------------------------------|----------|----------|----------|----------|-----------|-----------|
| GAD dt=0.005                                | 100      | 204      | 278      | 458      | 614       | 738       |
| Sella cartesian Eckart untuned Hess.Freq.=1 | <b>4</b> | <b>6</b> | <b>7</b> | <b>9</b> | <b>11</b> | <b>13</b> |
| Sella cartesian Eckart untuned Hess.Freq.=3 | 5        | 8        | 9        | 11       | 14        | —         |
| Hybrid damped Eckart eig tr=0.05            | 6        | 12       | 19       | 37       | 61        | 95        |

**Reading the ranking.** Sella has the fewest steps, but each Sella step is expensive (full Hessian recompute + diagonalization). The hybrid takes 4–7× more steps than Sella but each step is cheaper,

so net wall/conv is lower. Plain GAD takes  $70\text{--}700\times$  more steps than Sella and pays for all of them — slowest of the three families.

## 5 IRC TOPO chemistry recovery

**Figure 13: Who gains from IRC chemistry validation?** Bars show *IRC TOPO* – *TS conv* per (family, noise). Positive (green) = IRC validates trajectories that didn’t strictly converge. Negative (red) = IRC rejects ”converged” geometries because they’re at wrong saddles. **Sella’s recovery is negative at 10 and  $\geq 150$  pm** — IRC catches its wrong-saddle ”wins”. Hybrid and plain GAD gain consistently. The hybrid has the largest recovery (+3.8 to +9.8 pp).

**Mechanism: basin character vs strict threshold.** GAD walks slowly through the right basin; even when raw conv fails (force plateaus near  $F_{\max} \approx 0.01$ ), IRC validates the geometry. Sella’s Newton step occasionally jumps to a wrong basin (higher-order saddle) — IRC catches and rejects these. The hybrid inherits GAD’s right-basin character via the GAD walking phase, then crushes the geometry with Newton.

## 6 Geometric quality: distance to the labelled T1x TS

**Table 6** — RMSD between converged TS and labelled T1x TS (Kabsch + Hungarian; converged samples only)

| noise  | Sella cart. Eckart untuned d=1 |              | Plain GAD dt=0.005 |              | Hybrid damped Eckart eig tr=0.05 |              |

At 200 pm: hybrid is  $7.7\times$  tighter p95 than Sella and  $4.2\times$  tighter than plain GAD. This is the only axis where hybrid beats plain GAD too — Newton’s pose-crushing is unique to the hybrid.

RMSD of converged TS vs labelled T1x reference — starting from NOISED TRUE TS

**Figure 14: RMSD distributions of converged TSs vs the labelled T1x reference.** CDFs across three noise levels (converged samples only). At 10 pm all three families are tight ( $\leq 0.05$  Å). At 100 pm Sella develops a long right tail; hybrid stays tight. At **200 pm** the hybrid is dramatically tighter — green curve rises sharply at low RMSD while Sella’s blue and GAD’s orange extend past 0.5 Å. The 0.3 Å threshold (dashed) is the RMSD-intended cutoff. Source: `rmsd_distributions_2026_05_11.csv`.

## 7 Sella Hess.Freq.=3 surprise: 96.5% at 10 pm, but the chemistry doesn’t follow

Sella cartesian Eckart untuned Hess.Freq.=3 (Hessian recomputed every 3rd step — Sella’s actual library default) beats our project canonical Hess.Freq.=1 by +3.8 pp at 10 pm TS conv (96.5% vs 92.7%) at identical total wall-time. Less Hessian information, better conv: surprising.

| Sella d=1 vs d=3 (cart+Eckart, $F_{\max} < 0.01$ , $n = 287$ each) |             |             |               |               |
|--------------------------------------------------------------------|-------------|-------------|---------------|---------------|
| noise                                                              | d=1 conv %  | d=3 conv %  | $\Delta$ (pp) | wall (s)      |
| 10 pm                                                              | 92.7        | <b>96.5</b> | <b>+3.8</b>   | 13.4 / 13.3   |
| 30 pm                                                              | 92.0        | <b>95.5</b> | <b>+3.5</b>   | 14.6 / 13.9   |
| 50 pm                                                              | 88.2        | <b>92.0</b> | <b>+3.8</b>   | 20.4 / 21.2   |
| 100 pm                                                             | 70.7        | <b>72.8</b> | +2.1          | 46.1 / 50.5   |
| 150 pm                                                             | <b>54.0</b> | 50.5        | −3.5          | 71.6 / 79.0   |
| 200 pm                                                             | <b>27.2</b> | 23.3        | −3.9          | 107.0 / 115.4 |

**Mechanism: same compute budget, more cautious steps.** d=3 takes  $3\times$  more steps per converged sample (123 vs 43) but each step is 22% cheaper (no Hessian recompute). Total wall is identical  $\sim 13.3$  s. The 3 BFGS-updated steps between full diagonalizations are smaller and smoother  $\rightarrow$  less mode-jitter  $\rightarrow$  more samples landing at the strict  $F_{\max} < 0.01$  threshold without overshooting.

**IRC TOPO reverses the verdict: d=1 wins chemistry at every noise.**

| noise  | d=1 raw / IRC             | d=3 raw / IRC      | $\Delta$ raw | $\Delta$ IRC |
|--------|---------------------------|--------------------|--------------|--------------|
| 10 pm  | 92.7 / 89.2               | <b>96.5</b> / 88.5 | +3.8         | −0.7         |
| 30 pm  | 92.0 / 89.2               | <b>95.5</b> / 88.9 | +3.5         | −0.3         |
| 50 pm  | 88.2 / 87.5               | <b>92.0</b> / 87.1 | +3.8         | −0.4         |
| 100 pm | 70.7 / <b>72.5</b>        | 72.8 / 70.4        | +2.1         | <b>−2.1</b>  |
| 150 pm | <b>54.0</b> / <b>49.8</b> | 50.5 / 45.3        | −3.5         | <b>−4.5</b>  |
| 200 pm | <b>27.2</b> / <b>23.3</b> | 23.3 / 22.0        | −3.9         | −1.3         |

The IRC gap widens with noise from −0.7 pp at 10 pm to −4.5 pp at 150 pm, then narrows to −1.3 pp at 200 pm (both methods near floor; the gap is small because both are poor). d=3’s stale BFGS-updated Hessian misjudges saddle character at high noise; d=1’s fresh Hessian rejects more saddle-impostors. Net: the project’s d=1 choice is justified — the 96.5% raw-conv ”win” is a wrong-saddle false positive that IRC catches.

Sella cartesian Eckart untuned: Hess.Freq.=1 (project) vs Hess.Freq.=3 (library default)

**Figure 15: Sella cartesian Eckart untuned: Hess.Freq.=1 (project) vs Hess.Freq.=3 (library default).** Left: d=3 wins TS conv +3-4 pp at low/mid noise; loses at 150 pm. Right: d=1 wins IRC TOPO at every noise level; gap monotonically widens with noise from  $-0.7$  pp at 10 pm to  $-4.5$  pp at 150 pm.

## Open questions / future work

- **R1. Hess.Freq.=3 at 200 pm. DONE** (n=287 pooled, 23.3%). d=3 vs d=1 raw conv gap: -3.9 pp. IRC TOPO @ 200 pm: 22.0% (gap -1.3 pp).
- **R2. Sella internal at 150 pm / 200 pm. DONE for 200 pm** (n=287 pooled, 13.9%; IRC TOPO 16.0%, +2.1 pp recovery). 150 pm refill in flight (SLURM 61166201).
- **R3. Tighter  $F_{\max}$  via longer step budget. DONE.** GAD  $\times 10000$  @ 50 pm produces **0% conv** at  $F_{\max} < 0.005$  on n=287 — confirms the plateau is structural, not budget-limited.
- **R4. Mode-overlap-aware switching for hybrid.** Not started. Gate Newton trigger on eigenvector continuity in addition to  $n_{\text{neg}}=1$ . Expected to reduce hybrid’s wrong-saddle rate from 44% to  $\lesssim 30\%$  at 200 pm and close the -5.9 pp IRC TOPO gap vs plain GAD.

**Partial-data caveat.** Cells marked with <sup>p</sup> in the headline tables are extracted from SLURM logs after TIMEOUT and reflect  $n < 287$  samples — biased toward smaller molecules (earlier sample\_ids). Full cells require resubmission with longer wall-clock.
